

IN THE SPECIFICATION AMEND:

On page 6, please delete the first full paragraph and instead insert the following paragraph:

In the preferred embodiment, the anti-theft sensor assembly is composed of a housing having an interior region and an upper surface. The housing is configured to enable the anti-theft sensor assembly to be fixedly attached to the sensor region on the mounting member. The anti-theft sensor assembly includes a switch member for contacting the camera being monitored and is oriented substantially normal to an external surface on the camera. The housing contains an electronic circuit board for creating an electronic alarm signal upon interruption of the operable contact between the switch member and the surface of the camera being monitored. A signaling device indicates at least one of the presence and absence of operable, monitored contact between the switch member and the surface of the camera being [monitored, which transmits an electrical signal to an alarm signaling device through a signal transmission medium.] monitored. A signal transmission medium is used for transmitting the electronic alarm signal from the electronic circuit board to an alarm signaling device.

On page 9, please delete the first full paragraph and instead insert the following paragraph:

In the alternative preferred embodiment, the anti-theft sensor assembly includes a switch member for contacting the camera being monitored and is oriented substantially normal to an external surface on the camera. Also included in the anti-theft sensor assembly is an electronic circuit board for creating an electronic alarm signal upon interruption of the operable contact between the switch member and the surface of the camera being

monitored. A signaling device, indicates the presence and absence of operable monitored contact between the switch member and the surface of the camera being [monitored, which transmits an electrical signal to an alarm signaling device through a single transmission medium.] monitored. A signal transmission medium is used for transmitting the electronic alarm signal from the electronic circuit board to an alarm signaling device. A second threaded fastener adapted to mate with the first threaded hole in the mounting member to secure the electronic circuit board to the mounting member. Preferably, the switch member of the anti-theft sensor assembly is biased into operable contact with the external surface of the camera being monitored.

On page 11, please delete the second full paragraph and instead insert the following paragraph:

A preferred embodiment of a universal camera mount assembly 1 of the present invention is shown generally in Figs. 1-4. The universal camera mount assembly 1 includes a (universally mountable) mounting member 2 having an upper surface 3 and a lower surface 4. The mounting member has a plurality of at least three mounting holes 5 (indicated in Fig. 2 as 5a – 5l) that pass completely through the mounting member 2 beginning from the upper surface to the lower surface. The mounting holes 5 are oriented in any quantity of three or greater and in any pattern, but are shown in Figs. 1-3 as being oriented in linear rows and columns. The mounting member 2 has accommodations for placement of an electronic anti-theft sensor assembly 6 adjacent to the placement of the array of mounting [holes 4] holes 5 such that the array of mounting [holes 4] holes 5 is asymmetrically located with respect to the placement of the electronic anti-theft sensor assembly 6.

On page 11, please delete the last paragraph that continues onto the top of page 12 and instead insert the following paragraph:

In the preferred embodiment, the electronic anti-theft sensor assembly 6 may be secured to the mounting member by way of a layer of double-sided adhesive tape 7, although any number of alternative fastening methods 8, such as rivets, screws, etc, may be employed in combination with, or in place of, the double-sided adhesive tape. The electronic anti-theft sensor assembly 6 may be positioned on any of the upper surface, the lower surface, or in recesses of the upper or lower surfaces on the mounting member 2. The electronic anti-theft sensor assembly 6 includes an electro-mechanical switch 9 to enable operable contact with the article being monitored 10, such as a video or still camera. The electro-mechanical switch 9 is biased against compression, preferably by employing a resistive spring, such that the electro-mechanical switch 9 will trigger an electrical signal if the switch is displaced a pre-determined amount from its compressed position. In this manner, an electro-mechanical switch 9 may be induced to make substantial contact with a surface of the camera being monitored 10 such that if contact is lost, an electronic signal is transmitted to an [alarm system (not shown).] alarm signaling device 6a (as shown in Fig. 9). The transmission of the electronic signal to an alarm signaling device 6a may be made [utilizing] by utilizing any one of a variety of classical techniques, known in the art, including via a flexible electronic cable 11, cellular or terrestrial telephonic systems, radio frequencies, infrared, electro-magnetic, and the like.

On page 12, please delete the last paragraph that extends onto page 13 and instead insert the following paragraph:

Fig. 4 represents a cross sectional view of Fig. 2 of the preferred embodiment taken along site lines "4 - 4" and looking in the

direction of the arrows. The mounting member 2 mounted to the camera being monitored 10, is preferably also affixed to the camera by double-sided adhesive tape 12 positioned between the camera 10 and the mounting member 2. The double-sided adhesive tape 12 not only secures the mounting member 2 to the camera 10, but also creates a bond between mounting member 2 and camera 10 so as to preclude direct access to anti-theft sensor assembly 6 thereby preventing tampering with the functionality of the attached anti-theft sensor assembly 6 and its switch member 9; by limiting access to switch member 9 when in contact with camera 10. To further enhance the attachment between mounting member 2 and camera 10, a fastener 13 is inserted through one of the mounting holes 5a-I and is thereafter threaded into the pre-existing tripod mount hole that normally is present on a camera 10 to be monitored. The particular mounting hole 5a-I used is dependent upon the configuration and location of the tripod mount hole present on camera 10. [The user should chose] A user would choose the mounting hole within mounting member 2 that provides substantial contact of the upper surface of mounting member 2 to camera 10 while still maintaining substantial contact of anti-theft sensor assembly 6 and switch member 9 with camera 10. Upon securing the mounting member 2 to the camera being monitored 10, the electro-mechanical switch of the invention 9 necessarily makes contact with an external surface of the camera thereby placing the anti-theft sensor assembly 6 in its operable position to begin detecting any detachment of the camera from the universal mount assembly. In the preferred embodiment, the electronic anti-theft sensor assembly 6 incorporates a signaling feature 14, such as a light emitting diode, to serve as a visual alert to both the thief and the store personnel that intimate contact between the electro-mechanical switch 9 and a surface of the camera has been lost if the alarm circuit has been activated. In the event of an interruption of operable contact between the electro-mechanical switch 9 and the surface of the camera being
